On the storage of continuous "recordings" in TSV files (Michael Hanke)

Proposal: Switch from JSON to YAML

Introduction

Motivation

Neuroimaging experiments result in complicated data that can be arranged in many different ways. So far there is no consensus how to organize and share data obtained in neuroimaging experiments. Even two researchers working in the same lab can opt to arrange their data in a different way. Lack of consensus (or a standard) leads to misunderstandings and time wasted on rearranging data or rewriting scripts expecting certain structure. Here we describe a simple and easy to adopt way of organising neuroimaging and behavioural data. By using this standard you will benefit in the following ways:

- It will be easy for another researcher to work on your data. To understand the
 organisation of the files and their format you will only need to refer them to this
 document. This is especially important if you are running your own lab and anticipate
 more than one person working on the same data over time. By using BIDS you will save
 time trying to understand and reuse data acquired by a graduate student or postdoc that
 has already left the lab.
- There is a growing number of data analysis software packages that can understand data organised according to BIDS.
- Databases such a OpenfMRI.org accept datasets organised according to BIDS. If you
 ever plan to share your data publicly (nowadays some journals require this) you can
 minimize the additional time and energy spend on publication, and speed up the curation
 process by using BIDS to structure and describe your data right after acquisition.
- There are validation tools that can check your dataset integrity and let you easily spot missing values.

BIDS is heavily inspired by the format used internally by OpenfMRI.org. While working on BIDS we consulted many neuroscientists to make sure it covers most common experiments, but at the same time is intuitive and easy to adopt. The specification is intentionally based simple file

formats and folder structures to reflect current lab practices and make it accessible to wide range of scientists coming from different backgrounds.¹

Definitions

A **MRI session** is a set of MRI image acquisition procedures in which imaging data is measured from a participant. Sessions are equivalent to visits in a longitudinal study. During one session, one more more **MRI runs** may be acquired, each of which is a specific measure of brain structure or function that can be characterized by the type of information that the scan was designed to characterize. For example, different imaging scan acquisition types are used to characterize different aspects of brain structure, such as T1 weighted, T2 weighted and diffusion weighted MRI scans.

A session is therefore a set of coherent MRI acquisitions done in similar fashion across subjects, and, in general, subjects will stay in the scanner bed during a session. If for some reason a subject has to leave the scanner room and then be re-positioned on the scanner bed, the set of MRI acquisitions will still be considered as a session and match sessions acquired in other subjects. If several sessions are planned and performed on all -or most- subjects, often in the case of some intervention between sessions (e.g. training, etc), then several sessions would be defined (eg. pre and post behavioural session).

For functional runs, in addition to the options available for measuring different aspects of brain function (such as blood flow, blood volume, and blood oxygenation level), scans vary based on the experimental perturbations that are performed during or between scans to elicit specific changes in brain activity.

In some cases, these perturbations may be tasks in which a participant is presented with specific stimuli or asked to perform a function that is designed to elicit brain activity, they may be interventions such as exposure to drugs, or the participant may be asked to lie quietly. For simplicity, all of the different experimental perturbations are referred to as **tasks**², and a **task run** is a single consecutive measurement of the participant during the perturbation. Depending on the nature of the experiment, the participant may be exposed to several different perturbations during a task run, or may receive different perturbations in different task runs. A **protocol** provides an end-to-end specification of an MRI scan including the parameters used to acquire the scan and the task that was performed during the scan. For scanning acquisition, the protocol contains a list of the various scanning parameters that were used in order to optimize the measurement for the type of information that the scan was designed to characterize. For the task, the protocol consists of any instructions given to the participant along with the timing of the various experimental events (stimuli and responses) that occurred during the task scan. A **condition** is a specific category of events, an **onset** is the time at which the event began, and the **duration** is the amount of time that the event lasted.

¹ For review of other data organization standards in neuroimaging see Appendix.

² Please mind that according to this definition "resting state" is considered a task.

Compulsory, optional, and additional

The following standard describes a way of arranging data and writing down metadata for a subset of neuroimaging experiments. Some aspects of the standard are compulsory. For example a particular file name format is required when saving structural scans. Some aspects are regulated but optional. For example a T2 volume does not need to be included, but when it is available is should be saved under a particular file name specified in the standard. This standard aspires to describe a majority of datasets, but acknowledges that there will be cases that do not fit. In such cases one can include additional files (such as preprocessed data, phantom calibration data, etc.) to the existing folder structure following common sense.

The Inheritance Principle

Any metadata file (.json, .bvec, .tsv, etc.) may be defined at any directory level. The values from the top level are inherited by all lower levels unless they are overridden by a file at the lower level. For example, tasks.tsv may be specified at the participant level, setting TR to a specific value. If one of the series has a different TR than the one specified in that file, another tasks.tsv file can be placed within that specific series directory specifying the TR for that specific run.

Extensions

BIDS specification can be extended. Currently <u>Model and hypothesis specification</u> is one of such extensions.

File Format specification

Imaging files

Imaging data are stored using the NIfTI file format, preferably compressed NIfTI files (.nii.gz), either 1.0 or 2.0 version. Imaging data should be converted to the NIfTI format using a tool that provides as much of the NIfTI header information (such as orientation and slice timing information) as possible. Since the NIfTI standard offers limited support for the various image acquisition parameters available in DICOM files, we also encourage users to provide additional meta information extracted from DICOM files in a sidecar JSON file (with the same filename as the .nii.gz file, but with .json extension). This metadata can be easily extracted using DCMStack DICOM to NIFTI converter (https://github.com/moloney/dcmstack).

Tabular files

Other files are saved as tab delimited values (.tsv) files, aka csv files where commas are replaced by tabs. Tabs need to be true tab characters and not series of space characters. Therefore to avoid confusion files should not include more than one adjacent space character. Each TSV file need to start with a header line listing the names of all columns (with the exception for physiological and other continuous acquisition data - see below for details). Names need to be separated with tabs. String values containing tabs should be escaped using double quotes.

Missing values should be coded as "n/a".

Example:³

```
onset duration RT correct StopTrial GoTrial Was_it_red? 200 20 0 n/a n/a n/a n/a
```

Key/value files (dictionaries)

Javascript Object Notation Style (JSON) files will be used for storing key/value pairs. Extensive documentation of the format can be found here: http://json.org/. Several editors have built-in support for JSON syntax highlighting that aids manual creation of such files. An online editor for JSON with built-in validation is available at: http://jsoneditoronline.org.

Example:

```
{
    "RepetitionTime": 3.0,
    "Instruction": "Lie still and keep your eyes open"
}
```

Subject naming

Subjects (participants participants) should be assigned unique labels. Labels can consist of letters and/or numbers. If numbers are used we strongly encourage zero padding ("01" instead of "1" if you have more than nine subjects) to make alphabetical sorting more intuitive.

Units

Time should be expressed in seconds.

Describing dates and timestamps:

- Date time information should be expressed in the following format 2009-06-15T13:45:30
- Time information should be expressed in the following format: 13:45:30
- Dates can be shifted by a random number of days for privacy protection reasons. To
 distinguish real dates from shifted dates always use year 1900 or earlier when including
 shifted years. For longitudinal studies please remember to shift dates within one subject
 by the same number of days to maintain the interval information. Example:
 1867-06-15T13:45:30
- Age should be given as the number of years since birth. Using higher accuracy (weeks) should be avoided due to privacy protection.

Directory structure (single session example)

This is an overview of the folder and file structure. Because there is only one session, the session level is not required by the format. For details on individual files see descriptions in the next section:

³ Note that to make the display clearer, the second row does contain two successive tabs, which should not happen in an actual BIDS tsv file.

sub-control01

- anatomy
 - sub-control01_T1w.nii.gz
 - sub-control01 T1w.json
 - sub-control01 T2w.nii.gz
 - sub-control01 T2w.json

functional

- fieldmap
 - sub-control01_fieldmap_task-nback_phasediff.nii.gz
 - sub-control01_fieldmap_task-nback_phasediff.json
 - sub-control01_fieldmap_task-nback_magnitude1.nii.gz
- sub-control01_task-nback_bold.nii.gz
- sub-control01_task-nback_bold.json
- sub-control01_task-nback_events.tsv
- sub-control01 task-nback cont-physio.tsv
- sub-control01_task-nback_cont-physio.json
- sub-control01_task-nback_sbref.nii.gz

diffusion

- sub-control01 dwi.nii.gz
- sub-control01 dwi.bval
- sub-control01_dwi.bvec
- o sub-control01 scans.tsv
- Additional files and folders may be added as needed for special cases. They
 should be named using all lowercase with a name that reflects the nature of the
 scan (e.g., "calibration"). Naming of files within the directory should follow the
 same scheme as above (e.g., "sub-control01_calibration_Xcalibration.nii.gz")
- tasks.json
- participants.tsv
- dataset_description.json

Detailed file description

Dataset description

Template: dataset description.json

A JSON file describing the dataset. Following fields are mandatory:

- Name: name of the dataset
- Description: free form description of the experiment
- DescriptionFile: relative path to a file containing a description of the dataset In addition we encourage to fill those additional fields:
 - License: what license is this dataset distributed under? The use of license name abbreviations is suggested for specifying a license. A list of common licenses with suggested abbreviations can be found in appendix III.

- Authors: List of individuals who contributed to the creation/curation of the dataset
- Acknowledgements: who should be acknowledge in helping to collect the data
- HowToAcknowledge: Instructions how researchers using this dataset should acknowledge the original authors. This field can also be used to define a publication that should be cited in publications that use the dataset,
- Funding: sources of funding (grant numbers)
- References AndLinks: a list of references to publication that contain information on the dataset, or links.
- VersionHistory: a dictionary of versions and their corresponding changes. The last item in version history is the current version.

```
Example:
```

Anatomy imaging data

Template:

```
sub-<participant_label>/
    ses-<session_label>/
        anatomy/
        sub-<participant_label>_ses-<session_label>_T1w[_run<
        index>].nii.gz

sub-<participant_label>/
    anatomy/
    sub-<participant_label> T2w[_run<index>].nii.gz
```

Anatomical (structural) data acquired for that participant. Possible modalities include, but are not limited to:

Name	Suffix	Description
T1 weighted	_T1w_	
T2 weighted	_T2w_	
T1 map	_T1map_	quantitative T1 map (likewise for T2)
T2 map	_T2map_	quantitative T2 map
FLAIR	_FLAIR_	
Proton density	_PD_	
Combined PD/T2	_PDT2_	
Inplane T1	_inplaneT1_	T1-weighted anatomical image matched to functional acquisition
Inplane T2	_inplaneT2_	T2-weighted anatomical image matched to functional acquisition
Angiography	_angio_	
Defacing mask	_defacemask_	Mask used for defacing
Susceptibility Weighted Imaging (SWI)	_SWImagandphase_	Magnitude and corresponding phase images of the SWI

Several scans of the same modality can be acquired and will be indexed with a suffix: _run01, _run02, _run03 etc. When there is only one scan of a given type the suffix can be omitted. Please note that diffusion imaging data is stored elsewhere (see below). Metadata corresponding to each anatomical NifTi file can be provided in a JSON file with the same name but .json extension.

Task imaging data

Template:

```
sub-<participant_label>/
    functional/
    sub-<participant_label>_task-<task_label>[_run<index>]_bold.nii.gz
```

Imaging data acquired during BOLD imaging. This includes but is not limited to task based fMRI as well as resting state fMRI (i.e. rest is treated as another task). For task based fMRI a corresponding task events (see below) file must be provided. For multiband acquisitions, one can also save the single-band reference image as type "sbref" (e.g. sub-control01_task-nback_sbref.nii.gz).

Each task has a unique label consisting of letters and/or numbers (other characters including spaces and underscores are not allowed). Those labels has to be consistent across subjects and sessions. If more than one run of the same task has been acquired a suffix: _run01, _run02, _run03 etc. can be used. If only one run was acquired the suffix can be omitted.

Some meta information about the acquisition need to be provided in an additional JSON file. Required fields:

- RepetitionTime: The time in seconds between the beginning of an acquisition of one
 volume and the beginning of acquisition of the volume following it (TR). Please note that
 this definition includes time between scans (when no data has been acquired) in case of
 sparse acquisition schemes.
- TaskName: Name of the task (for resting state use the "rest" prefix). No two tasks should have the same name. Task label is derived from this field by removing all non alphanumeric ([a-zA-Z0-9]) characters.

Other recommended metadata include:

- SliceTiming: The time at which each slice was acquired during the acquisition. Slice timing is not slice order it describes the time (sec) of each slice acquisition in relation to the beginning of volume acquisition. It is described using a list of times (separated by spaces) referring to the acquisition time for each slice. The list goes through slices along the slice axis in the slice encoding direction. This parameter is required for sparse sequences. In addition without this parameter slice time correction will not be possible.
- PhaseEncodingDirection: The phase encoding direction, specified as e.g, RL for right-to-left encoding or AP for anterior-to-posterior. Note that this is not the same as the DICOM term InPlanePhaseEncodingDirection which can have "ROW" or "COL" values. This parameter is required if a corresponding fieldmap data is present.
- EffectiveEchoSpacing: The sampling interval also known as the dwell time; required for unwarping distortions using field maps; expressed in seconds. See here how to calculate it. This parameter is required if a corresponding fieldmap data is present.
- EchoTime: The echo time (TE) for the acquisition, specified in seconds. May be
 multiple values separated by spaces for multi-echo acquisitions. This parameter is
 required if a corresponding fieldmap data is present. Corresponds to
 http://neurolex.org/wiki/Category:Echo Time.
- FlipAngle: Flip angle for the acquisition, specified in degrees. Corresponds to: http://neurolex.org/wiki/Category:Flip_Angle.
- MultibandAccelerationFactor: The multiband factor, for multiband acquisitions
- ParallelReductionFactorInPlane: The parallel imaging (e.g, GRAPPA) factor. Corresponds to http://neurolex.org/wiki/Category:Parallel Reduction Factor In-plane.

- ParallelAcqusitionTechnique: The type of parallel imaging used (e.g. GRAPPA, SENSE). Corresponds to
 http://neurolex.org/wiki/Category:Parallel Acquisition Technique.
- Instructions: Text of the instructions given to participants before the scan. This is
- especially important in context of resting state fMRI and distinguishing between eyes open and eyes closed paradigms.
- TaskDescription: Longer description of the task.
- CogAtlasID: URL of the corresponding Cognitive Atlas Task term
- CogPOID: URL of the corresponding CogPO term

When adding additional metadata please use camel case version of <u>DICOM ontology terms</u> whenever possible.

Example:

If this information is the same for all participants, sessions and runs it can be provided in task<task_number>_bold.json (in the root directory of the dataset). However, if the information differs between the file it can be specified in the

```
sub-<participant_label>/functional/sub-<participant_label>_task-<task
_label>_run<run_number>_bold.tsv file. If both files are specified the one
corresponding to a particular participant, task and run takes precedence.
```

Task events

Template:

Where <matches> corresponds to task file name. For example:

```
sub-control01_task-nback
```

The purpose of this file is to describe timing and other properties of events recorded during the scan. Those can be both stimuli presented to the participant, or participant responses. Each task events file requires a corresponding task imaging data file. The first two columns are mandatory and should contain "onset" and "duration" in that order. Both should be expressed in seconds (not milliseconds). Timing should be measured from the beginning of the acquisition of the first volume in the corresponding task imaging data file. Therefore negative numbers in "onset" are allowed⁴ (however "duration" needs to be always positive). For event related designs "duration" can be set to 0 to indicate an instantaneous event (i.e a delta function). An arbitrary number of additional columns can be added. Those allow describing other properties of events that could be later referred in modelling and hypothesis extensions of BIDS.

Example:

```
sub-control01/
    functional/
        sub-control01_task-nback_events.tsv
onset    duration    trial_type response_time
1.2     0.6     go     1.435
5.6     0.6     stop     1.739
```

References to existing databases can also be encoded using additional columns. Example 2 includes references to the Karolinska Directed Emotional Faces (KDEF) database⁵:

Example2:

```
sub-control01/
     functional/
          sub-control01 task-nback events.tsv
          duration trial type identifier database
onset
                                                   response time
1.2
          0.6
                    afraid AF01AFAF
                                                   1.435
                                         kdef
5.6
          0.6
                                                   1.739
                                         kdef
                    angry
                             AM01AFAN
5.6
          0.6
                    sad
                              AF01ANSA
                                         kdef
                                                   1.739
```

Physiological and other continuous recordings

Template:

⁴ For example in case there is an in scanner training phase that begins before the scanning sequence has started events from this sequence should have negative onset time counting down to the beginning of the acquisition of the first volume.

⁵ http://www.emotionlab.se/resources/kdef

Where <matches> corresponds to task file name. For example:

```
sub-control01_task-nback
Optional: yes
```

Physiological recordings such as cardiac and respiratory signals can be specified using two files: a TSV file with data (without header line) and a JSON for storing start time, sampling frequency, and name of the columns from the TSV. Please not that in contrast to other TSV files this one does not include a header line. Instead the name of columns are specified in the JSON file. This is to improve compatibility with existing software (FSL PNM) as well as make support for other file formats possible in the future. Start time should be expressed in seconds with relation of the time of acquisition of first volume in the series (negative values are allowed). Sampling frequency should be expressed in Hz. The following naming conventions should be used:

- cardiac: continuous pulse measurement
- respiratory: continuous breathing measurement
- trigger: continuous measurement of the scanner trigger signal

Any combination of those three can be included as well as any other potentially stimuli related continuous variables (such as low level image properties in a video watching paradigm).

More than one continuous recording file can be included (with different sampling frequencies). In such case use different labels. For example: cont-physio, cont-movie labels.

Example:

```
sub-control01/
     functional/
           sub-control01 task-nback cont-physio.tsv
34
           110
44
           112
                           0
2.3
           100
                           1
sub-control01/
     functional/
           sub-control01 task-nback cont-physio.json
{
    "SamplingFrequency": 100.0,
    "StartTime": -22.3,
    "Columns": ["cardiac", "respiratory", "trigger"]
}
```

Diffusion imaging data

Template:

Diffusion-weighted imaging data acquired for that participant, together with bvec and bval files in the FSL format⁶: The bvec files contain 3 rows with n space-delimited floating-point numbers (corresponding to the n volumes in the relevant Nifti file). The first row contains the x elements, the second row contains the y elements and third row contains the z elements of a unit vector in the direction of the applied diffusion gradient, where the i-th elements in each row correspond together to the i-th volume with [0,0,0] for non-diffusion-weighted volumes.

.bvec example:

```
0 0 0.021828 -0.015425 -0.70918 -0.2465
0 0 0.80242 0.22098 -0.00063106 0.1043
0 0 -0.59636 0.97516 -0.70503 -0.96351
```

The bval file contains the b-values (in s/mm²) corresponding to the volumes in the relevant Nifti file), with 0 designating non-diffusion-weighted volumes, space-delimited.

```
<u>.bval example:</u>
0 0 2000 2000 1000 1000
```

.bval and .bvec files can be saved on any level of the directory structure and thus define those values for all sessions and/or subjects in one place (see Inheritance principle).

⁶ http://fsl.fmrib.ox.ac.uk/fsl/fsl4.0/fdt/fdt_dtifit.html

In case multiple identical sequences with varying phase encoding direction were acquired (for distortion correction) a JSON file should be provided. The file should contain phase encoding direction ([PA, AP, RL, LR, HF. FH]) for use in b0 distortion correction. In addition the Total Readout Time specified as time in seconds between from the center of the first echo to the center of the last echo (see here and here how to calculate it).

```
.json example:
{
    "PhaseEncodingDirection": "PA",
    "TotalReadoutTime": 0.000095,
}
```

Fieldmap data

Data acquired to correct for B0 inhomogeneities can come in different forms. The current version of this standard considers four different scenarios. Please note that in all cases fieldmap data can be linked to a specific scan it was acquired for by filling the <matches> substring with the corresponding label (for example ses002_task-nback_run01).

<u>Case 1: Phase difference image and at least one magnitude image</u> Template:

```
sub-<participant label>/
     <functional|diffusion>/
           fieldmap/
                <matches> phasediff.nii.gz
sub-<participant label>/
     <functional|diffusion>/
           fieldmap/
                <matches> phasediff.json
sub-<participant label>/
     <functional|diffusion>/
           fieldmap/
                <matches> magnitude1.nii.gz
(optional)
sub-<participant label>/
     <functional|diffusion>/
           fieldmap/
                <matches> magnitude2.nii.gz
```

Where <matches> corresponds to task or DWI file name. For example:

```
sub-control01_task-nback
```

This is a common output for build in fieldmap sequence on Siemens scanners. In this particular case the sidecar JSON file has to define the Echo Time Difference parameter which is defined as Echo Time of the second phase image acquisition minus Echo Time of the first phase image acquisition. For example:

```
"EchoTimeDifference": 0.00246
}
Case 2: Two phase images and two magnitude images
Template:
sub-<participant_label>/
           <functional|diffusion>/
                fieldmap/
                      <matches> phase1.nii.gz
sub-<participant label>/
           <functional|diffusion>/
                fieldmap/
                      <matches> phase1.json
sub-<participant label>/
           <functional|diffusion>/
                fieldmap/
                      <matches> phase2.nii.gz
sub-<participant label>/
           <functional|diffusion>/
                fieldmap/
                      <matches> phase2.json
sub-<participant label>/
     <functional|diffusion>/
           fieldmap/
                <matches> magnitude1.nii.gz
sub-<participant label>/
     <functional|diffusion>/
           fieldmap/
                <matches> magnitude2.nii.gz
```

```
Where <matches> corresponds to task or DWI file name. For example: sub-control01 task-nback
```

Similar to the case above, but instead of a precomputed phase difference map two separate phase images are presented. The two sidecar JSON file need to specify corresponding EchoTime values. For example:

```
"EchoTime": 0.00746,
}
```

Case 3: A single, real fieldmap image (showing the field inhomogeneity in each voxel)

Template:

Where $\verb|<matches|| > corresponds to task or DWI file name. For example:$

```
sub-control01_task-nback
```

In some cases (for example GE) the scanner software will output precomputed fieldmap denoting the B0 inhomogeneities. In this case the sidecar JSON file need to include the units of the fieldmap. The possible options are: "Hz", "rad/s", or "Tesla". For example:

```
"Units": "rad/s",
}
```

Case 4: Two opposite phase encoded directions (topup)

Template:

This technique combines two Spin Echo EPI scans with different phase encoding directions. In such a case, the phase encoding direction is specified in the filename (<phase_enc_dir1> and <phase_enc_dir2>) as well as the corresponding JSON file as one of: "PA", "AP", "LR", "RL", "HF", "FH". For these differentially phase encoded sequences, one also needs to specify the Total Readout Time defined as the time (in seconds) from the center of the first echo to the center of the last echo (see here and here how to calculate it). For example

```
{
    "PhaseEncodingDirection": "PA",
    "TotalReadoutTime": 0.000095,
}

Scans key file
Template:
sub-<participant_label>/
    sub-<participant_label>_scans.tsv
```

Optional: yes

The purpose of this file is to describe timing and other properties of each imaging acquisition sequence (each .nii.gz file) within one session. Each .nii.gz file should be described by at most one row. Relative paths to files should be used under a compulsory "filename" header. If acquisition time is included it should be under "acq_time" header. Datetime should be expressed in the following format 2009-06-15T13:45:30 (year, month, day, hour (24h), minute, second; this is equivalent to the RFC3339 "date-time" format, time zone is always

assumed as local time). For anonymization purposes all dates within one subject should be shifted by a randomly chosen (but common across all runs etc.) number of days. This way relative timing would be preserved, but chances of identifying a person based on the date and time of their scan would be decreased. Dates that are shifted for anonymization purposes should be set to a year 1900 or earlier to clearly distinguish them from unmodified data. Shifting dates is recommended, but not required.

Additional fields can include external behavioural measures relevant to the scan. For example vigilance questionnaire score administered after a resting state scan.

Example:

```
filename acq_time functional/sub-control01_task-nback_bold.nii.gz 1877-06-15T13:45:30 functional/sub-control01_task-motor_bold.nii.gz 1889-06-15T13:55:33
```

Participant key file

Template:

(single session case)

participants.tsv

The purpose of this file is to describe properties of participants such as age, handedness, gender etc. In case of single session studies this file has one compulsory column "participant_id" followed by a list of optional columns describing participants. Each participant needs to be described by one and only one row.

Single session example:

```
participant_id age sex group
sub-control01 34 M control
sub-control02 12 F patient
sub-patient01 33 F control
```

Longitudinal studies with multiple sessions (visits)

Multiple sessions (visits) are encoded by adding an extra layer of directories and file names in the form of "ses-<session_label>". Session label can consist only of alphanumeric characters [a-zA-Z0-9] and should consistent across subjects. If numbers are used in session labels we recommend using zero padding (for example ses-01, ses-11 instead of ses-1, ses-11). This makes results of alphabetical sorting more intuitive. Acquisition time of session can be defined in the sessions file (see below for details).

Sessions file

Template:

sub-<participant_label>/

```
sub-<participant_label>_sessions.tsv
```

In case of multiple sessions there is an option of adding an additional participant key files describing variables changing between sessions. In such case one file per participant should be added. These files need to include compulsory "session_id" column and describe each session by one and only one row. Column names in per participant key files has to be different from group level participant key column names.

Multiple sessions example:

```
      session_id
      acq_time
      systolic_blood_pressure

      ses-predrug
      2009-06-15T13:45:30
      120

      ses-postdrug
      2009-06-16T13:45:30
      100

      ses-followup
      2009-06-17T13:45:30
      110
```

Appendix I: Glossary:

- **Session** is a continuous MRI image acquisition procedure in which imaging data is measured from a participant. During a session, more than one run can be acquired. Session correspond to visits in longitudinal studies.
- Run is an MRI data acquisition, a specific measure of brain structure or function that can be characterized by the type of information that the scan was designed to characterize. For example, different imaging scan acquisition types are used to characterize different aspects of brain structure, such as T1 weighted, T2 weighted and diffusion weighted MRI scans. For functional scans, in addition to the options available for measuring different aspects of brain function (such as blood flow, blood volume, and blood oxygenation level), runs vary based on the experimental perturbations that are performed during or between scans to elicit specific changes in brain activity.
- Protocol provides an end-to-end specification of an MRI scan including the parameters
 used to acquire the scan and the task that was performed during the scan. For scanning
 acquisition, the protocol contains a list of the various scanning parameters that were
 used in order to optimize the measurement for the type of information that the scan was
 designed to characterize.
- **Event** is a stimulus presented to a participant or a direct or indirect participant response. Blocks of in fMRI tasks are also treated as event, but with longer duration.
- **Onset** is the time at which the event began expressed in seconds.
- Duration is the amount of time that the event lasted expressed in seconds.
- **Session** is one continuous visit of a subject to the scanning facility during which participant may enter the scanner multiple times.

Appendix III: Licenses

This section lists a number of common licenses for datasets and defines suggested abbreviations for use in the dataset metadata specifications

PD	Public Domain	No license required for any purpose; the work is not subject to copyright in any jurisdiction.
PDDL	Open Data Commons Public Domain Dedication and License	License to assign public domain like permissions without giving up the copyright: http://opendatacommons.org/licenses/pddl/
CC0	Creative Commons Zero 1.0 Universal.	Use this if you are a holder of copyright or database rights, and you wish to waive all your interests in your work worldwide: https://creativecommons.org/about/cc0

What is below is <u>not part of the specificat</u> i	ions: brainstorming/material/
idea	

if people are working on the openfmri extensions, here are things to consider:

- sparse/non-sparse acquisitions (sparse acquisitions require TR and TA and whether the acquisition was triggered by stimuli or whether acquisition was periodic)
this can be handled through a is sparse boolean key in scan key

- metadata at:
- dataset level

From Satra's mail:

- participant level
- visit level

(some demographics should go here things like age will change across visits, gender might change as well)

 links to cognitive paradigms in tasks perhaps this goes into experiment.yaml/json/rdf

This section is a brainstorming on how do we go from the condition_key.tsv to the design matrix of the regression model. We thought about three options.

1) Keep the model description at a high level and have models following R or patsy (https://patsy.readthedocs.org/en/v0.1.0/formulas.html) but this may be constraining: many decisions are made on the parametrisation of the model without control of the user.

- 2) Design a low level description that would allow a precise specification of the design matrix from the condition_key.tsv.
- 3) Have both, low level is generated from high level. Users will in general specify a high level model, but can specify a low level model.

Another question is the first level versus second level.

- At the first level, regressors are obtained either from conditions (that are convolved with Hrf and subsampled), or are covariates already sampled at each TR. While we could have these two in the same file, I think it would simplify things to have two separate files. This also raise the question of the movement parameters. These are not yet computed when the data is submitted to openfMRI and thus require a symbolic notation.
- At the second level, regressors of dimension the number of participants should be specified (age, gender, scanner type, etc). If we want to allow for more complex models,

then we will need the full fledge model description (between / within factors, etc). Unlikely to be solved now (unless we just follow R conventions for specification of mixed models).

Intra series (run) model: A, B are columns found in the condition_key.

Operators:

- 1) +: A+B: create variable containing the onsets times of both A and B. From the example of SST: GoTrial+StopTrial will create a variable with all Go and Stop onsets.
- 2) *: A*B: use to create the interaction between conditions A and B.
- 3) (A < | > | <= | >= | == | <> | B): element-wise create a boolean. Typically, create a boolean condition from a quantitative value (say, keep events that have RT less than 1s)
- 4) Hrf(A) :convolve by Hrf. Can specify if derivatives of the Hrf are used. Hrf(A, 'dt', 'dd') : 'dt': with time derivative, ''dd': with dispersion derivative.
- 5) M(A): mean center A. Use to mean center regressors.
- 6) #(A, B, C, ...): orthogonalize A wrt to B; then C, ...
- 7) **: A ** B: Used to create the full interaction space between factors with several levels.
- 8) []: slicing
- 9) {}: stack horizontally
- 10) I: Intercept

Example of models:

```
tsv will contain: var1, var2, RT, Diff, mvt_0..5
a1 = Hrf(var1)
a2 = Hrf(var2)
a1x2 = Hrf(var1*var2)
model = {a1, a2, a1x2, #(Hrf(var1*RT, {a1,I}), mvt_0, ..., mvt_5, I}
```

This reads: conditions 1, 2, their interaction, and the condition1 modulated by RT and orthogonalized wrt to a1 and I (ie mean centered).

Use Cases:

I've been thinking for some time that data hosts (i.e. XNAT) should provide image-level unique identifiers (such as DOI or other). Then, when a query generates a set of data for some other use, this new set contains a collection of all the identifiers of the source data, so that credit and utilization can be tracked more efficiently. While I'm open to discussion about the exact nature of this identifier, I do like to think of it in terms of the types of structure and functions that DOI's provide already, so I'll couch the use case in DOI terms until we replace the DOI with a different construct, just for the sake of concreteness. A DOI has a specified schema and set of fields that we can usurp for our data citation purposes: Author (person who collected the data), publisher (data host), etc. Included is a pointer to the actual data. While in the minimalist sense, this

pointer to the data could be a pointer to a NIfTI file (or zipped DICOM dataset). The DOI (or other unique specifier system) specification will not itself include all the metadata that a data host knows about the data. Thus, it would be better that the data pointer was a wrapper for the image and its known metadata. I think the BIDS structure (with our without its NIDM specification) would be a good target wrapper for this data pointer. One could also imagine XCEDE, or any of a number of other wrapper systems. Each dataset, via it's unique identifier, would also have a 'landing page' where the permitted metadata could be exposed, but access to the data itself regulated by a variety of data use agreements. This is in very close analogy to how DOI's for publications work.

I would like to experiment with this, in the XNAT instance of NITRC-IR and would like to use a beta (alpha?) version of the BIDS specification with a minimal metadata set to represent 'simple' datasets of structure, diffusion and resting-state example cases. Even if this fails, I think it will be important to learn how it fails so that we can build a more robust way to foster these data unique identifiers.

More thoughts will be forming on this in a separate document for imaging data DOIs. https://docs.google.com/document/d/1nH4MECcQ1G1W70vfkr7rACFBYRWnsJY4mAKIW3Obe e0/edit

Proposal:

Multiple event files. Each needs onset and duration, but can include extra columns (different for each file). Events will have optional but unique suffixes. Devs can do events*.tsv.

On the storage of continuous "recordings" in TSV files (Michael Hanke)

Compression:

I propose to permit compressed storage for data files of continuous recordings. Nobody edits these things by hand of you have tens of thousands of lines and the storage/bandwidth benefits are significant. A quick test on my data shows that for cardiac/respiratory recordings the compressed file size is typically <10% (gzip) or <5% (XZ) of the original uncompressed TSV. GZIP support is already required for NIfTI IO, so it could be a good compromise.

Proposal: Switch from JSON to YAML

Here is a dataset description JSON file that I made by hand to get an impression what users would need to do:

```
{
    "Name": "studyforrest",
    "Description": "This dataset contains versatile brain imaging data for natural auditory stimulation and real-life cognition. It includes high-resolution functional
```

magnetic resonance (fMRI) data from 20 participants recorded at high field strength (7 Tesla) during prolonged stimulation with an auditory feature film ('Forrest Gump'). In addition, a comprehensive set of auxiliary data (Tlw, T2w, DTI, susceptibility-weighted image, angiography) as well as measurements to assess technical and physiological noise components have been acquired. Participants were also scanned with a musical genre stimulation paradigm...",

```

```

The raw file is here: http://kumo.ovgu.de/~mih/dataset_description.json

Overall it was an unpleasant experience. It took me almost an hour and 8 validator runs to get it JSON compliant. The most frustrating thing is the fact that JSON cannot handle multi-line strings, hence no changelog items without lists. Consequently, the missing line-break are not a mistake, but an effect of JSON's limitations.

Next I created the same description in <u>YAML</u>. Took less than a quarter of the time, and only 3 validator runs to figure out that YAML is more picky re indentation than Python. Below is how a full description would look like. Based on that I'd propose to reconsider the choice of JSON.

```
# one can have comments
Name: studyforrest # even here

# the '>' removes newlines from multi-line text and treats empty lines like
# paragraphs, similar to latex

VersionHistory:

1:

- Initial release (Jan 22 2014)

2:

- Physiological data fixes and additions (Feb 20 2014)
- physiological data for all participants in original sampling rate (physio_pristine.txt.gz) was added
- physiological data for sub008 run005 was updated to strip leading data samples prior to the fixes MR trigger signal. Thanks to Christine Guo for the report
- trigger log for first MR trigger (only) was offset by one data sample (5--10ms)

3:

- Bug fixes, aggregate data (Jun 16 2014)
- Individual brain mask images from non-linear alignment had only the linear transformation component applied to them. Consequently the masks did not match the brain outline. This release contains the

fixed brain mask images. No other data was modified.

- Include aggregate data (mean, median, min, max, std) for more than 200 regions-of-interests taken from the Harvard-Oxford cortical and sub-cortical atlas, as well as the Juelich brain atlas shipped with FSL. See the scripts in 'scripts/parcellation_ts/' in gumpdata source code repository for details. Data is available in CSV and HDF5 format.

4:

- NIfTI header fixes (Sep 29 2014)
- task-nback BOLD images reported a wrong volume repetition time of $\sim\!24\mathrm{s}$

in

the NIfTI header field pixdim[4] (MRIConvert issue). This release updates the images to the correct value of 2.0s.

5:

- task002 data added; emotion annotation, fixes (Apr 06 2015)
- New 7T fMRI data with music stimulation (task002).
- New group and per-subject EPI template images based on all available 7T data.
- Re-aligned task-nback BOLD data using the new templates.
- Updated, now frame-accurate annotation of movie scene boundaries.
- Frame accurate camera shot annotation for the audio-visual movie (task003).
- Multi-observer emotion annotation for the audio-visual and audio-movie stimulus (see Reich et al. F1000Research 2015).

6:

- task002 bug fix (Jun 15 2015)
- Strip all samples prior to the first trigger from task002 physio data to homogenize with task-nback.
- Physio data for task002, sub005 runs 3 and up were mis-numbered and run008 was missing, due to a conversion error that did not take the aborted run into account. All runs are available and correctly numbered now.
- Remove invalid log files for behavioral data of sub020, task002, runs005-8. Subject aborted after run004.
- Add acquisition protocol for task002.
- Add task002 experiment implementation and stimulus files.
- Homogenize task002 stimulus file names with release experiment implementation.

7:

- task002 stimulus auditory features (Jun 17 2015)
- Add extracted auditory features for task002 stimuli (incl. source code). Thanks to Michael Casey for this contribution.
